

# Advent of Code

Day Eight

LucidBrot

August 2020

## 1 About

The task at adventofcode 2019 day 8 is fairly straightforward itself. It can be summarized as

Read the input line of  $N$  numeric characters into *layers* of size  $width * height$  (which are known) to find the layer that contains the lowest number of zeros. Then return the number of '1' digits multiplied by the number of '2' digits within that layer.

However, we're doing this in  $\text{\LaTeX}$ , which is typeset in spongebob-case for a reason.

## 2 The $\text{\LaTeX}$ Experience

First of all, we're doing something that it was not meant to be used for – so that means we never get the search results we want. Searching about arrays in  $\text{\LaTeX}$  for example gives you an explanation about how to typeset matrices. Very useful, but not what I wanted. Thankfully, the pgfplots sourceforge page contains a pdf with *Notes On Programming in  $\text{\TeX}$* .

Secondly, there don't seem to be any variables. Just *counters*, *counts* which are the  $\text{\TeX}$  version. and *ifdefs* and most importantly *macros*. But I did not read up on the internals of  $\text{\TeX}$  and  $\text{\LaTeX}$ , so I have no clue about the exact way that macros are evaluated. Sometimes you can define a command that works perfectly well for a constant argument, but if you dare use it on the

result of another command, you're being had from multiple directions. Because that result has not already been evaluated (expanded) and is passed as-is into the other command. My version of pdfLaTeX does not feature the primitive `\expanded` yet. Using `\expandafter` feels very clunky. Luckily there's a hack around that to be found here. And sometimes the problem was actually the `xstring` package which also breaks the hack.

The macros of this package are not purely expandable, i.e. they cannot be put in the argument of an `\edef`. Nestling macros is not possible neither.

For this reason, all the macros returning a result (i.e. all excepted the tests) have an optional argument in last position. The syntax is `[ name ]`, where name is the name of the control sequence that will receive the result of the macro: the assignment is made with an `\edef` which make the result of the macro name purely expandable. Of course, if an optional argument is present, the macro does not display anything.<sup>[1]</sup>

After eliminating some problems of this sort by storing the result in a new command by virtue of the optional argument, the same problem still appeared because some commands just don't work due to the same issue, even if they are making use of the optional argument to return that in turn (See Figure 1, Figure 2).

(Btw, I have used `\autoref` above, for the second figure reference, instead of `\ref` and that is pretty cool.)

```
\def\getchar[#1]#2{%
\StrMid{#1}{#2}{\numexpr #2 + 0\relax}[\mychar]%
\mychar}
```

Figure 1: This command does not like to be used on a non-constant string.

Finally, the performance of the `xstring` package is whack. It takes more than two minutes to figure out the length of a 15'000 character string. The bash command `wc -c inputfile.txt` does that in less than a second.

Figure 2: The difference between wrong code that compiles (red) and seemingly correct code that produces a compiler error (green).

### 3 StrLen

Since `xstring`'s `StrLen` is so slow, how about creating a faster one? We'll just have to run `tex` with the `--shell-escape` flag.[2] ( See Figure 3). Using that allows us to escape to the shell - which is either `bash` or the windows `cmd.exe`.

Figure 3: TeXworks settings for shellescape

A simple `\input{"echo test"}` already works! test!

But I cannot figure out how to correctly call `wc -c inputfile.tex` because the shell spawns in the wrong path. And also, for some reason the following code does not even create a file `outfile.blubb` anywhere on my machine.

```
\input{"echo a > outfile.blubb"}
```

The problem seems to be, according to the logs, that the pipe closes before the left side is finished writing to stdout. But that is actually happening due to the `echo` earlier. When I leave it out, that's not logged.

Maybe using python is easier? You'd have to read the source to get this one though.[3]

```
\begin{pycode}{abc}
print(1+12)
```

`\end{pycode}`

But no, that also results in a problem with writing to a file... So let me try something I understand!

```
\input{|"python -c "print(1+2);"}
```

3

And as you should be able to see, it works!

So for computing stringlength, a quick python call should speed things up.

```
\input{|"python -c "print(len('mystringofunkownlength'));"}
```

22

It is notable that spaces within that string get lost before they are passed to python. Thankfully we don't need this here. But this reminds me of PyAuCalc.

We can make L<sup>A</sup>T<sub>E</sub>X paste a string into that as well...

```
\def\mystr{hello}  
\def\mystrtwo{\mystr}  
\input{|"python -c "print(len('\mystrtwo'));"}
```

5 ...but for some reason it fails when used with our included inputstring. There's a site with an example on how to include text from a file, but it does not work at all for me[4]. I guess I'll just hardcode it inside this file here instead... For that, however, the line length limit becomes an issue. So I've declared 74 commands and combined them into one. Aand turns out that also didn't help. The string just ends after some two hundred characters.

So to quote a professor of mine, J. Hromkovic, "**Strategy: We Give Up!** What can we do to still be able to state something impressive?". Well, I can just hardcode the damn string length. That's not really worse than hardcoding the input.

## 4 Get Head Performance

Again, `xstring` is extremely slow with big strings. So I split everything into layers of 100 chars. But that's still noticeably slower at the end of the layer than at the start of the layer... even though it's only supposed to be a quick

character access. So I'm transforming everything into head accesses at index zero.

## 5 Scoping

Nested loops require scoping around the inner loop. Which in turn means we need to use the `\global` keyword to assign to variables from outside the inner scope. And that in turn makes it really weird to use `StrGobbleLeft` from the `xstring` package when I'm trying to remove a character and store the result back in the same string.

The solution is probably a rewrite that uses only one loop plus an if condition that checks the modulus of the loop counter and acts appropriately whenever a layer is finished.

## 6 Execution: Getting our Feet Wet

We had 34 Strawberries for this year's harvest. Probably not enough. So we are sad now and solve <https://adventofcode.com/2019/day/8>.

h e

6

000000201222100001

hello world 3 3 300

Image Width: 3      Image Height: 2

I want to loop 6 times for the first layer.

The input file contains 18characters.

```

\newcounter{outerloopcounter}
\setcounter{outerloopcounter}{0}
\loop
    \addtocounter{outerloopcounter}{1}
    \theouterloopcounter ,
    \ifnum \value{outerloopcounter}<3
\repeat
outerloopcount: \theouterloopcounter

```

Figure 4: Simple Loop using TeX Counters

## 7 Execution: The Water Is Cold

`\global` is a TeX command that declares the following definition or assignment to be global, meaning that if TeX is currently inside a group, the definition or assignment will still remain valid when the group is over. Commands that can follow `\global` include `\def`, `\edef`, `\let`, `\count`, `\countdef`, [...][5]

An alternative to using globals would be to use tikz loops with the `remember` option [6]. Another option I see is using counters instead of counts - they are the latex version of the tex counter. For counters, you can apparently not use `\the \ctr`, you have to use `\thectr` (See Figure 4).

Now let us do the same thing again, but with nested loops. See Figure 5. That requires curly braces around the inner loop. Otherwise, only the first outer loop iteration is run.

For the actual implementation, we assume that we are given `inputstringlength`, `imgwidth`, and `imgheight`. Computing those from the input string is feasible but takes long.

I'm using an `edef` to overwrite the `workingline` variable every loop.

Computation starting with 3 Layers of size 3x2.

Normally, I would do a first loop for finding the best Layer and a second block for extracting the relevant information. However, given that the loops are so slow with all those string operations, I'll just spend some brain overhead and do this in one loop, even if it is a bit harder to keep the overview.

```

\newcounter{outerloopcounter}
\setcounter{outerloopcounter}{0}
\newcounter{innerloopcounter}
\loop
    \setcounter{innerloopcounter}{0}
    \addtocounter{outerloopcounter}{1}

    {\loop
        \addtocounter{innerloopcounter}{1}
        (\theouterloopcounter , \theinnerloopcounter )
        \ifnum \value{innerloopcounter}<2
            \repeat }

        \ifnum \value{outerloopcounter}<3
    \repeat
outerloopcount: \theouterloopcounter

```

New Best Layer is Layer 2.

(3, 1)

The current char 1 does not equal 0.

About to remove 1chars from head

(3, 2)

The current char 0 equals 0.

About to remove 1chars from head

(3, 3)

The current char 0 equals 0. Skipping Layer 3 because it has more zeros than (i.e. it is worse than) Layer 2.

About to remove 3chars from head

outerloopcount: 3

Best Layer: 2 with 1 zeros.

It has 1 Ones and 4 Twos.

This is a total of  $n_{\text{ones}} \cdot n_{\text{twos}} = 4$ .

## 8 Todo

Once this is done, I should inform the person who said I should inform them once this is done, to be found at Twitter.

I should probably also put the shellescape stuff into an optional branch.  $\cap$ .
